Supplementary Fig. 1. Switching of antiepileptic drugs (first, second, and third choices). This graph shows a trend in the used medications. Most of the patients were treated effectively by the first or second drug. In particular, VPA and the VPA-LTG combination provided effective seizure control and were maintained as the first drug [16 of 23 (69.6%) and 8 of 8 (100%) patients, respectively]. The ESM and LTG groups exhibited lower maintenance rates for the first drug [12 of 22 (46.9%) and 8 of 14 (37.5%) patients, respectively]. This graph excludes two patients who were treated with other drugs such as zonisamide. ESM: ethosuximide, LTG: lamotrigine, VPA: valproate.
